

could u simulate if CTO team put in place these instructions and sleeves - can we beat Dov's benchmarks?

Thought for a few seconds

Yes — **but not automatically.**

With these instructions implemented correctly, the system could plausibly move toward Dov’s benchmark, but only if the **new alpha sleeves actually add independent return streams.** ADD/MRTP/Kelly alone will not get us to Sharpe/Sortino/Calmar > 1.5.

Rough simulation logic

Current base:

Version	Sharpe	CAGR	DD
V7.6α	~0.82	~3.2%	~-10.3%
V7.7 ADD-only	~0.80	~2.7%	~-8.6%

So governance alone is around:

Sharpe 0.8, good DD control, but insufficient absolute return.

To beat Dov, V7.8 must add **uncorrelated alpha sleeves.**

Plausible V7.8 outcome ranges

Conservative implementation

Metric	Estimate
Sharpe	0.9–1.1
Sortino	1.1–1.3
Calmar	0.5–0.8

Good improvement, but **not enough.**

Strong implementation

If momentum + relative value + volatility/convexity + mean reversion each contribute independently:

Metric	Estimate
Sharpe	1.2–1.6
Sortino	1.5–2.0
Calmar	1.0–1.6

This can **approach or beat Dov’s bar**.

Excellent implementation

If sleeves are genuinely low-correlated and ADD/MRTP prevents crashes:

Metric	Estimate
Sharpe	1.5–1.9
Sortino	1.8–2.4
Calmar	1.5–2.2

This would be institutional-quality.

The key condition

To beat Dov’s benchmarks, PolyAgora must not just reduce risk.

It must do this:

- Keep V7.6α governance advantage

+ preserve upside

+ add 3–5 independent alpha sleeves

+ reduce correlation to SPY/TLT/HYG

+ control drawdown with ADD/MRTP

+ size only stable edges with soft Kelly

My honest estimate

If CTO implements only ADD + soft Kelly:

No — probably not enough.

If CTO implements **ADD + soft Kelly + real alpha sleeves + low-correlation constraint**:

Yes — possible, but needs proof by walk-forward backtest.

Target for first CTO test:

Metric	Minimum internal target
Sharpe	> 1.2
Sortino	> 1.5
Calmar	> 1.0
DD	< 8%
Correlation to SPY	< 0.35

Then iterate toward:

Sharpe / Sortino / Calmar > 1.5 net of costs.
