

Yes — this list is useful, but **not as “strategies to trade directly.”** Use it as a **strategy-factory / validation layer** inside PolyAgora.

Best integration into PolyAgora

1. Strategy Candidates = Raw Material

The AI quant system can generate/test many strategies: momentum, mean reversion, volatility, carry, cross-sectional, event-driven, etc. But in PolyAgora they should enter only as **candidate sleeves**, not as trusted alpha.

2. PolyAgora adds the missing governance layer

The uploaded system already has strong validation: leakage control, shift(1), walk-forward, purged CV, deflated Sharpe, critic/risk/memory agents, kill-switches.

But PolyAgora should sit **above** this and ask:

In which semantic regime / block is this strategy admissible?

So each strategy receives:

Strategy → Validation score → Regime fit → Block fit → Zone permission → Kelly

3. Convert strategies into “sleeves”

Each accepted strategy becomes a sleeve with metadata:

```
{
  "strategy_id": "mom_6m_skip_1m_volnorm",
  "type": "momentum",
  "horizon": "weekly/monthly",
  "regime_affinity": ["Risk-On", "Trend", "Liquidity Stable"],
  "failure_modes": ["rate shock", "vol spike", "crowded unwind"],
  "polyagora_block": "B",
  "zone_permission": {
    "zone_1": "full",
    "zone_2": "reduced",
    "zone_3": "minimal",
    "zone_4": "off_or_hedged"
  }
}
```

4. Use Fixed Star / SM to decide when strategies are allowed

The key PolyAgora move:

A strategy is not judged only by Sharpe.
It is judged by whether it survives under the active regime ordering.

So:

`S_strategy, regime = 1`

means:

this strategy remains structurally coherent when run inside that regime.

If not, it is masked or resized.

5. Add Kelly only after PolyAgora gating

Order should be:

AI Strategy Factory
→ Validation Gates
→ PolyAgora Regime / Fixed-Star Gate
→ ADD / VAIDM / Buffett Qualifying Filters
→ Kelly deformation
→ Portfolio allocation

Not:

Strategy Sharpe → Kelly → allocation

because that would amplify fragile strategies.

The CTO instruction

Build a **Strategy Sleeve Registry**:

For every generated strategy:

1. Store code hash, hypothesis, economic mechanism.
2. Store IS/00S metrics, DSR, drawdown, kurtosis, capacity.
3. Map strategy to PolyAgora block/regime.
4. Define admissible zones.
5. Define failure modes.
6. Compute correlation to existing sleeves.
7. Allow allocation only if:
 - validation passes,
 - regime fit passes,
 - Fixed-Star/SM permission passes,
 - qualifying polygons do not veto.

In one sentence

Use the AI quant list as PolyAgora's **alpha-sleeve generator**, while PolyAgora remains the **semantic governance engine** deciding which sleeves are admissible, when they enter, how large they get, and when they are killed.
