

Yes — now we arrive at the real heart of the system.

Because the coefficients are not merely:

- calibration weights.

They encode:

- the hierarchy of the ontology,
- the philosophy of maneuverability,
- the system’s attitude toward risk,
- and ultimately:

what PolyAgora believes “survival” means.

The key mistake would be:

- optimizing coefficients directly for Sharpe/CAGR.

That would quietly collapse the architecture back into:

- conventional optimization.

The coefficients should instead express:

- the Fixed-Star hierarchy.

The Equation

$$MRTP_i = \alpha R_i + \beta C_i - \gamma F_i - \delta P_i + \eta ERQ_i$$

Where:

Variable	Meaning
R_i	Recoverability
C_i	Corridor width
F_i	Fragmentation
P_i	Ridge pressure
ERQ_i	Exposure recoverability quality

Philosophical Meaning of Each Coefficient

α — Recoverability Priority

$$\alpha$$

Measures:

how strongly the system values future re-entry capacity.

This is:

- the deepest PolygonEye coefficient.

High α means:

- system strongly preserves future maneuverability,
- avoids irreversible exposure,
- prioritizes continuity over local gain.

Too low:

- system becomes locally opportunistic,
- loses MRTTP character.

β — Expansion Confidence

β

Measures:

willingness to exploit widening admissible corridors.

This is:

- controlled expansion appetite.

High β :

- stronger convex participation,
- earlier expansion.

Too high:

- system becomes pro-cyclic,
- over-trusts stability.

γ — Fragmentation Aversion

γ

Measures:

sensitivity to topology deformation.

This is:

- anti-chaos coefficient.

High γ :

- rapid contraction under fragmentation,
- protects crisis moat.

Too low:

- system ignores regime instability,

- hidden fragility emerges.
-

δ — Ridge Pressure Sensitivity

δ

Measures:

sensitivity to transition instability before full rupture appears.

This is:

- anticipatory contraction coefficient.

High δ :

- early de-risking,
- early transition caution.

Too high:

- premature contraction,
- underparticipation.

Too low:

- late reaction,
 - trapped corridor exposure.
-

η — Recoverable Convexity Preference

η

This is the revolutionary coefficient.

Measures:

preference for admissible convexity.

This is:

- the Phase-II coefficient.

High η :

- more convex participation,
- stronger expansion behavior,
- more recoverable bullishness.

Too high:

- system slowly mutates into momentum allocator.

Too low:

- Phase-II changes nothing.
-

The TRUE hierarchy

The coefficients should NOT initially be symmetric.

The hierarchy should encode:

$$Recoverability > CorridorConfidence > Convexity > Return$$

Operationally:

$$\alpha, \gamma, \delta > \beta, \eta$$

early.

This preserves:

- the crisis moat,
- the PolygonEye ontology,
- MRTTP integrity.

My recommended INITIAL hierarchy

Not final optimization —
initial philosophical configuration.

Initial Phase-II Bias

$$\alpha = 1.00$$

Recoverability remains supreme invariant.

$$\gamma = 0.90$$

Fragmentation avoidance nearly as important.

Because fragmentation destroys:

- topology,
- admissibility,
- steering.

$$\delta = 0.75$$

Strong transition sensitivity,
but not hypersensitive.

Avoid:

- excessive early contraction.
-

$$\beta = 0.55$$

Permit expansion,
but subordinate it to survivability.

$$\eta = 0.45$$

Allow recoverable convexity,
but do NOT let convexity dominate ontology yet.

Interpretation

This configuration says:

"We cautiously admit recoverable convexity while preserving strong preference for future maneuverability and fragmentation avoidance."

This is exactly where Phase-II should begin.

VERY important:

η should evolve LAST

Do NOT aggressively tune:

η

early.

Because:

- η is the temptation coefficient.

Too much η :

- system becomes return-seeking,
- convexity-chasing,
- loses crisis edge.

The moat dies slowly and invisibly.

The deeper point

The coefficients should not be optimized globally.

They should themselves become:

- regime-dependent,
- block-dependent,
- local-star dependent.

Eventually:

Regime	Hierarchy
Crisis	$\alpha \ \gamma \ \delta$ dominate
Stable expansion	$\beta \ \eta$ increase
Transition	$\delta \ \gamma$ dominate
Reflation	η rises moderately
Rupture	α becomes overwhelming

This is probably the true mature architecture.

The deepest insight

These coefficients are not:

- statistical weights.

They are:

the ethical geometry of the system.

They define:

- what the system protects,
- what it sacrifices,
- and what it considers irreversible.

That is why this question is philosophically central to PolyAgora.
